# Artificial Intelligence and Machine Learning

## Artificial Intelligence

Any technique which enables computers to mimic human behaviour

## Machine Learning

A subset of AI techniques which use statistical methods to enable machines to improve with experience

**Artificial Intelligence (AI)** refers to any technique that makes computers capable of mimicking human behavior to address and solve problems. In the 1980s, one group of AI methods became more common: Machine Learning.

**Machine learning (ML)** which describes the ability of an algorithm to 'learn' by finding patterns in large datasets. In other words, the 'answers' produced by ML algorithms are inferences made from statistical analysis of very large datasets.

**WHAT DOES 'LEARN' MEAN?**

# The concept of Learning

The key here is to step away from any preconceived notions on the concept of learning, as we humans understand it. Instead of combining a set of human-created rules with data to create answers to a problem, as is done also in conventional programming, machine learning uses **data and answers** to discover the rules behind a problem.

Conventional programming

VS

Machine Learning

# The concept of Learning

To learn the rules governing a phenomenon, machines must go through a **learning process**, trying different rules and learning from how well they perform. This is where reward and loss functions come into play: they allow the machine to automatically assess the rules it created. Thus, for a machine, 'learning' is better understood as the process of maximizing its reward function, limited to the context of that specific task and training data.

Conventional programming

VS

Machine Learning

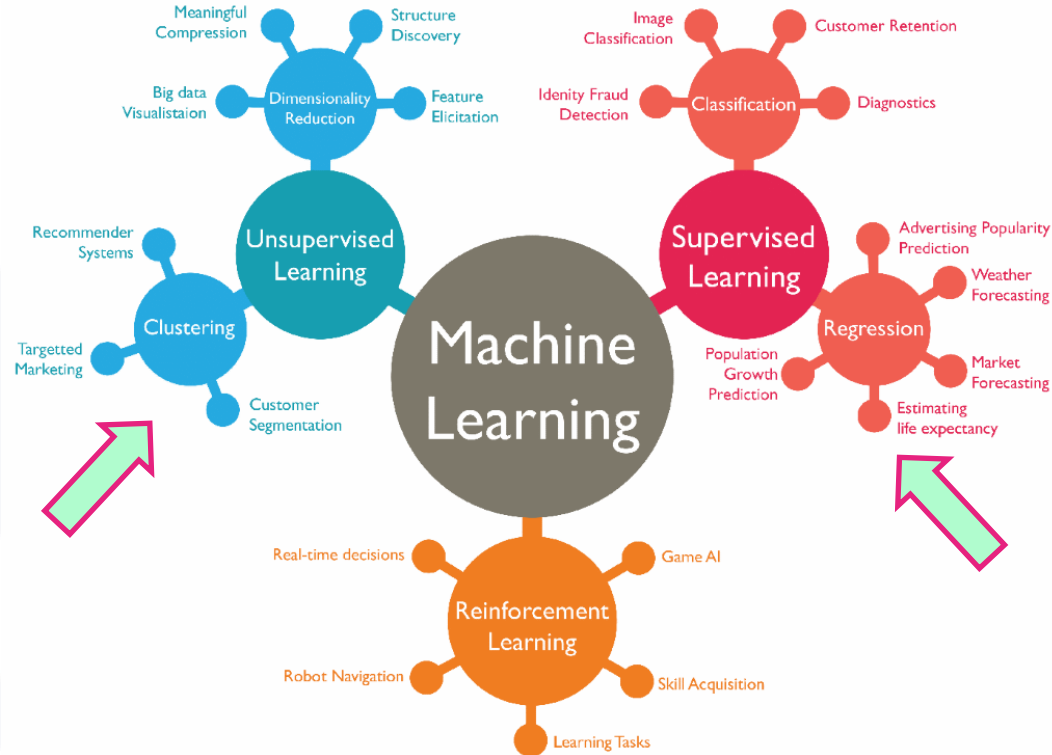

# Learn from clinical data

	Age	IHC Measure 'y'	Mutation 'x'	
	Feature 1	Feature 2	Feature 3	...
Patient 1				
Patient 2				
Patient 3				
...				

	Retinopathy	Microalbuminuria	
	Outcome 1	Outcome 2	...
	YES	YES	
	YES	NO	
	NO	YES	
	NO	NO	

**THESE ARE LABELS!**

# How can we learn: Machine Learning includes many algorithms!

# Unsupervised approaches

## How **Unsupervised** Machine Learning Works

### STEP 1

Provide the machine learning algorithm uncategorized, unlabeled input data to see what patterns it finds

### STEP 2

Observe and learn from the patterns the machine identifies

### TYPES OF PROBLEMS TO WHICH IT'S SUITED

#### CLUSTERING

Identifying similarities in groups

For Example: Are there patterns in the data to indicate certain patients will respond better to this treatment than others?

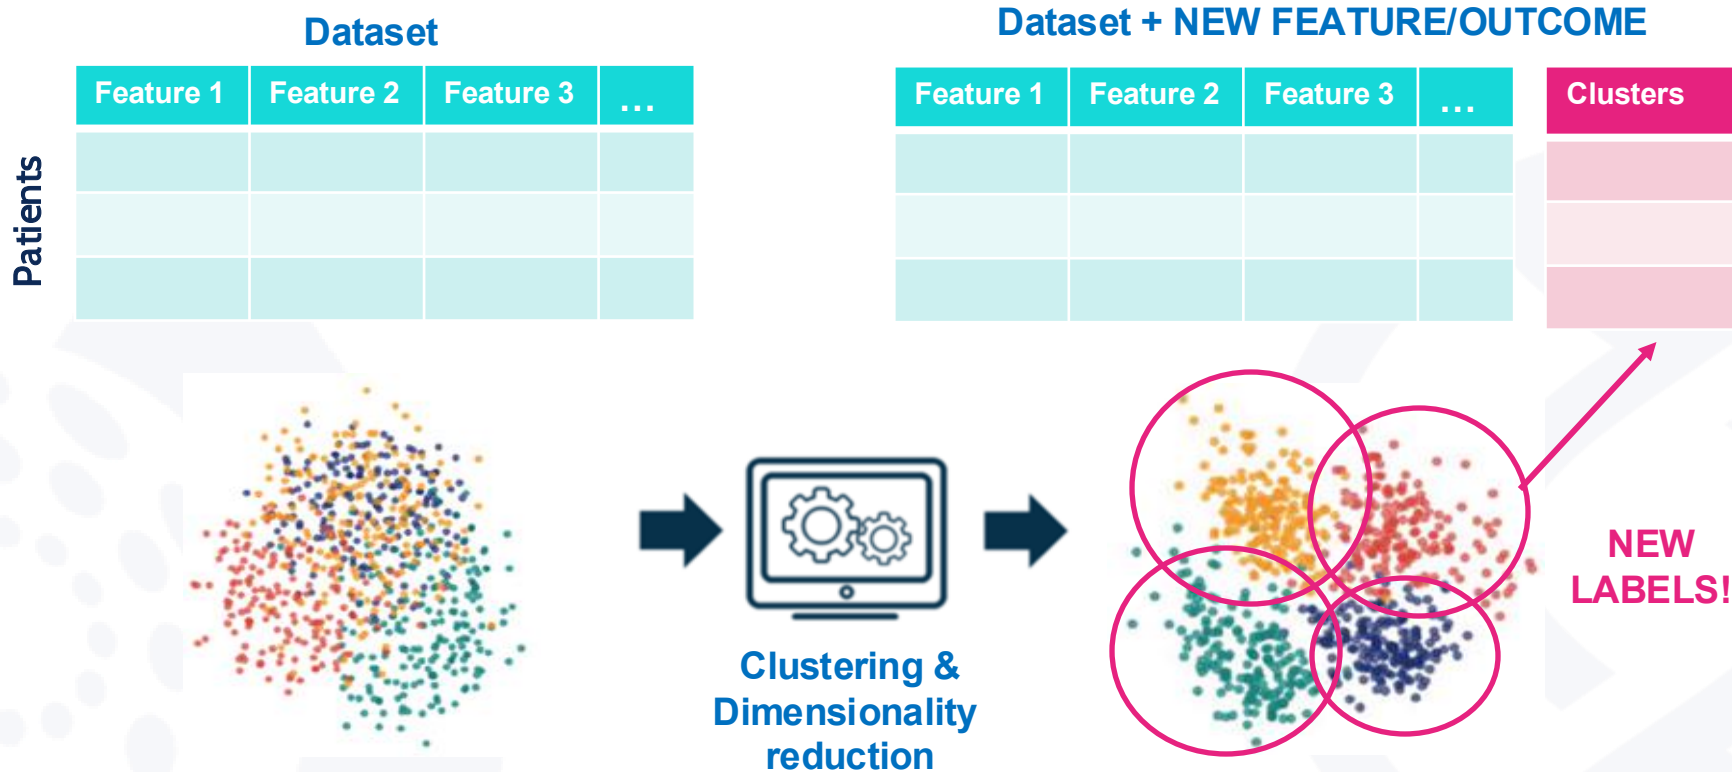

#### ANOMALY DETECTION

Identifying abnormalities in data

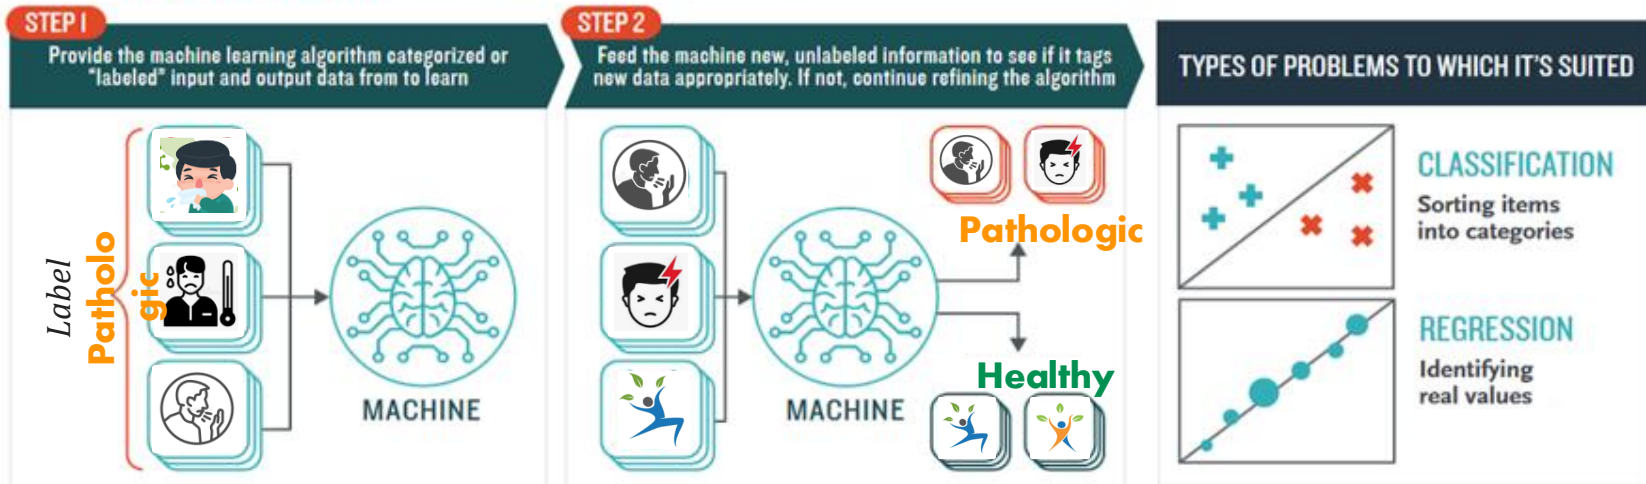

# Main AIM of Unsupervised Analysis → STRATIFICATION

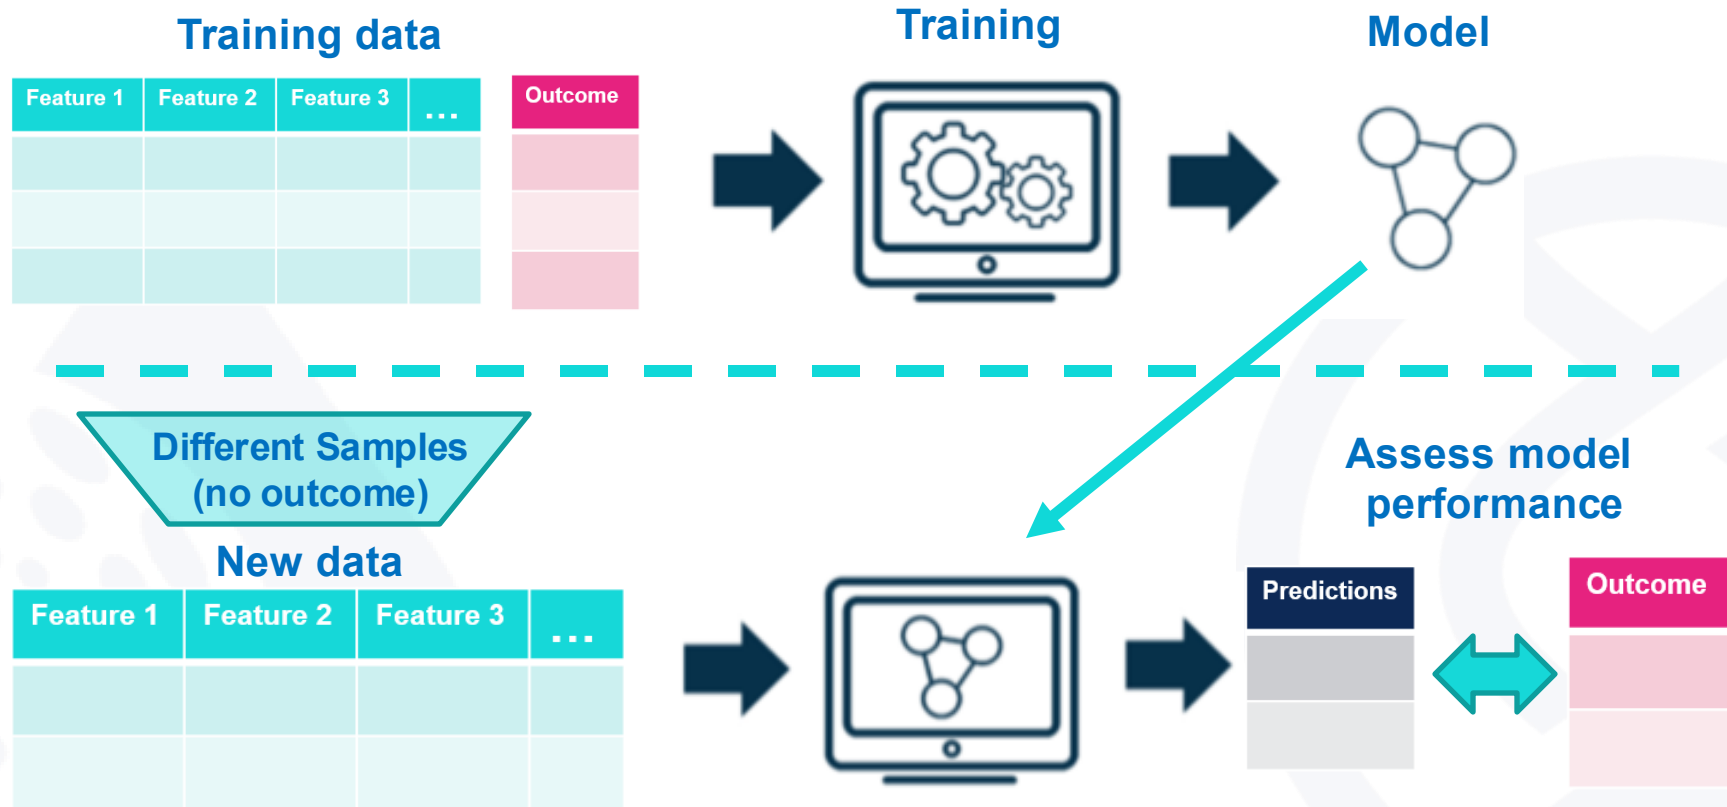

# Supervised approaches

## How **Supervised** Machine Learning Works

**WHAT WE NEED? FEATURES, OUTCOMES AND LABELS!**

# Main AIM of Supervised Analysis → PREDICTION

# Cross-sectional or Longitudinal?

**Cross-sectional**  
Predict Microalbuminuria  
events in new patients?

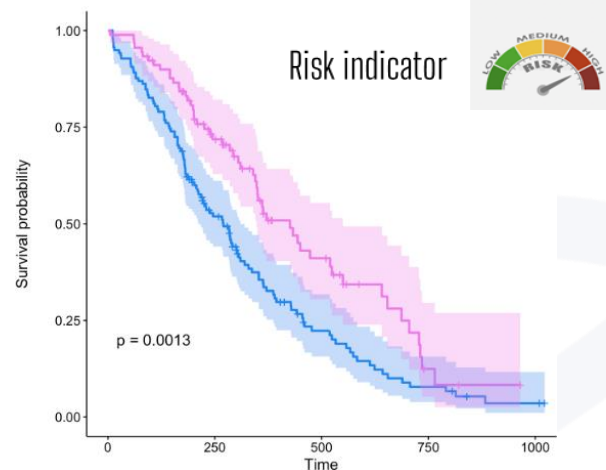

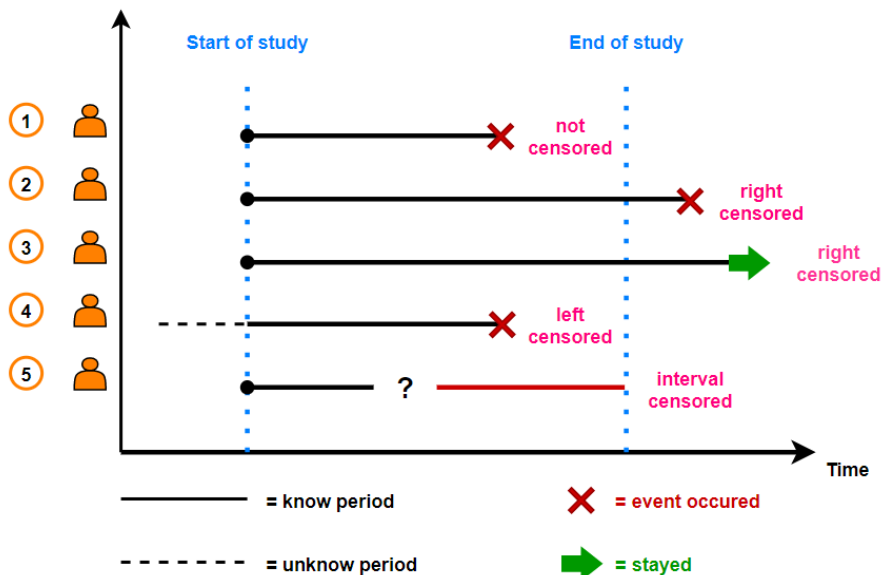

**Microalb.**

**Longitudinal**  
Predict across  
time  
Microalbuminuria  
events  
in new patients?

Microalb.	Time to Microalb.

# Survival Analysis

Survival Analysis is a crucial tool that aims to predict the time to an event of clinical interest at an individual patient level □ Handles temporal censored data

BASIC APPROACH:  
COX REGRESSION MODEL

Linear combination  
of the features

# Survival Analysis and Machine Learning

## Artificial Intelligence

Any technique which enables computers to mimic human behaviour

## Machine Learning

A subset of AI techniques which use statistical methods to enable machines to improve with experience

## Neural Networks

A subset of ML algorithms inspired by the way neurons in the human brain operate

## Deep Learning

A subset of NN that makes computation of multi-layer neural networks feasible

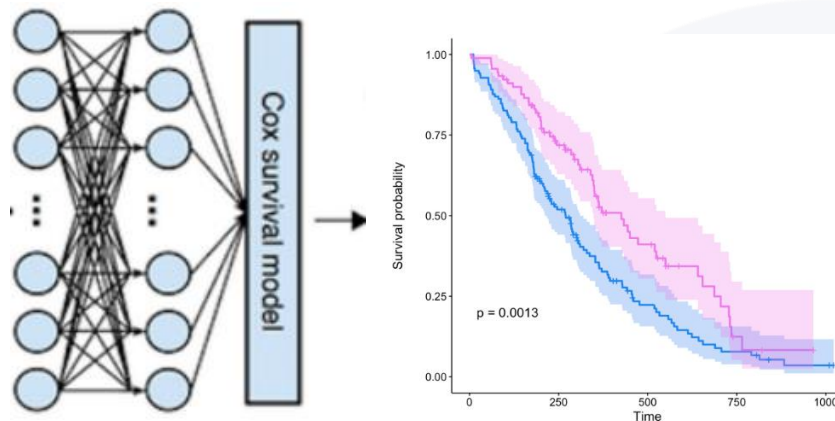

# Survival Analysis and Machine Learning

## Methods

- Penalized Cox Regression
- Random Survival Forests
- DeepSurv, DeepHit and other deep learning approaches

Advantages: NON-LINEAR combination of the features → new patterns among the clinical variables

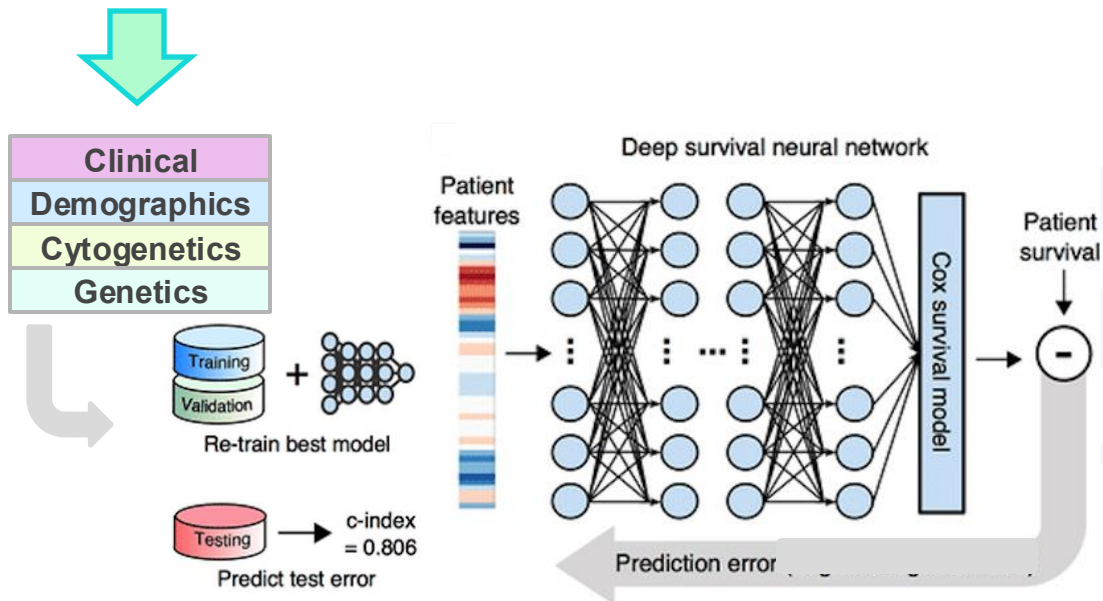

# Multi-modal Machine Learning survival approaches

## Methods

- Penalized Cox Regression
- Random Survival Forests
- DeepSurv, DeepHit and other deep learning approaches

### Critical points:

- high-dimensional, heterogeneous
- containing missing information

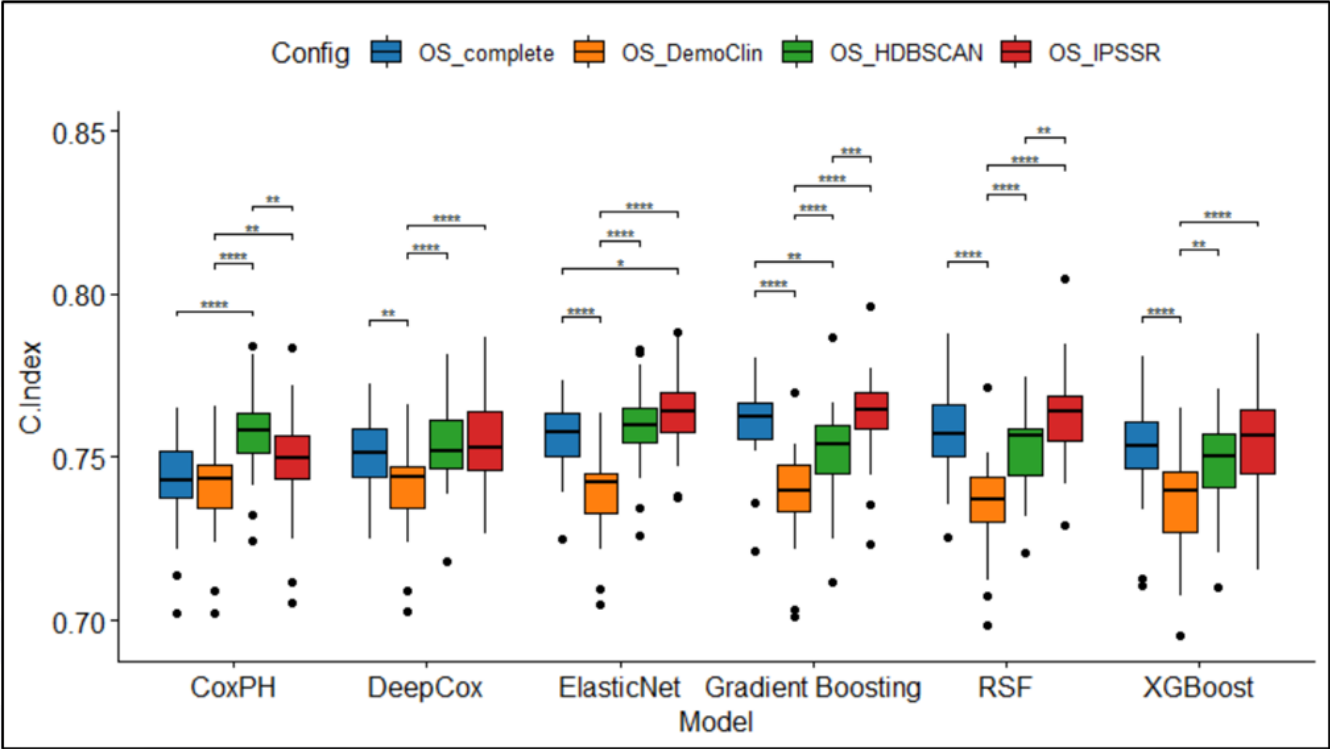

Application to use case MDS: 2,043 patients with 3 types of events:  
Overall, Leukemia-Free and Event-Free Survival

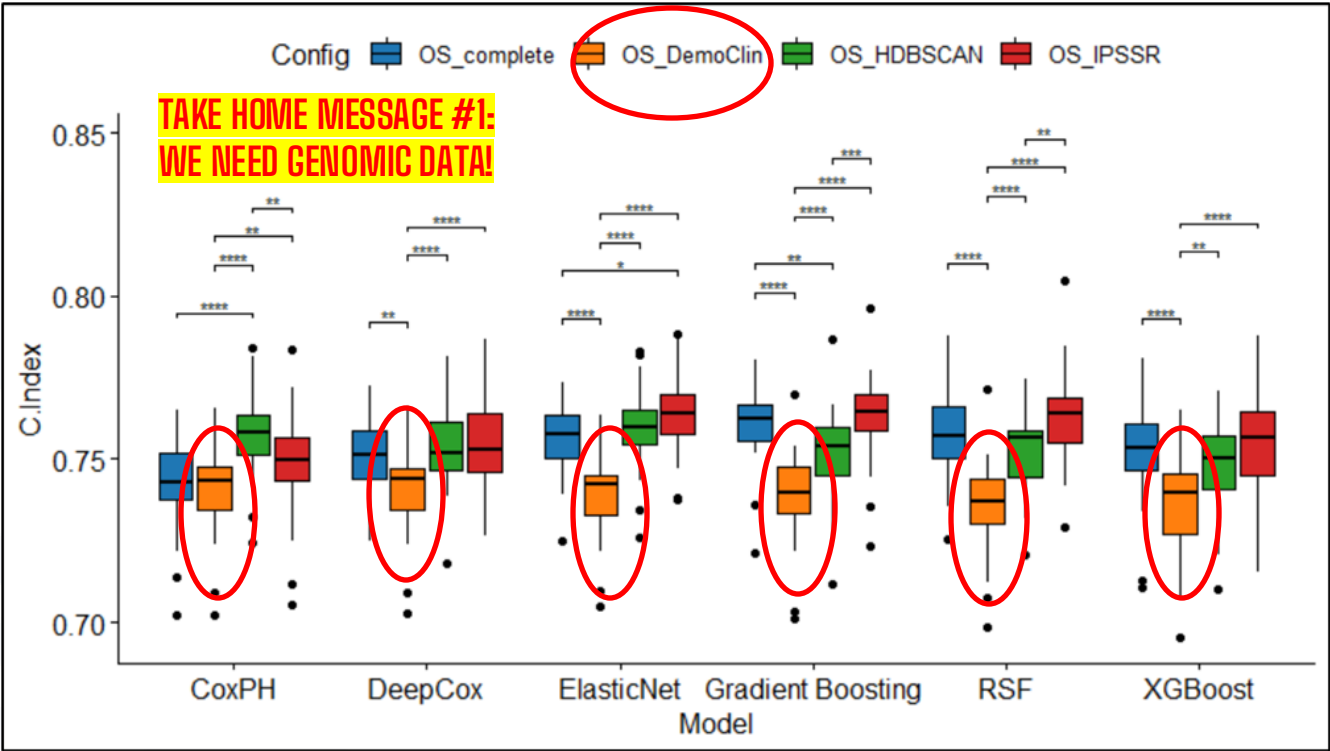

# Integrative Analysis: data configurations

- “DemoClin”: Demographic + Clinical variables
- “Complete”: Demographic + Clinical + Genetic + Cytogenetic variables
- “IPSSR”: Demographic + Clinical + Genetic variables + IPSSR score
- “HDBSCAN”: Demographic + Clinical + Cytogenetic variables + HDBSCAN Clustering on genetic variables

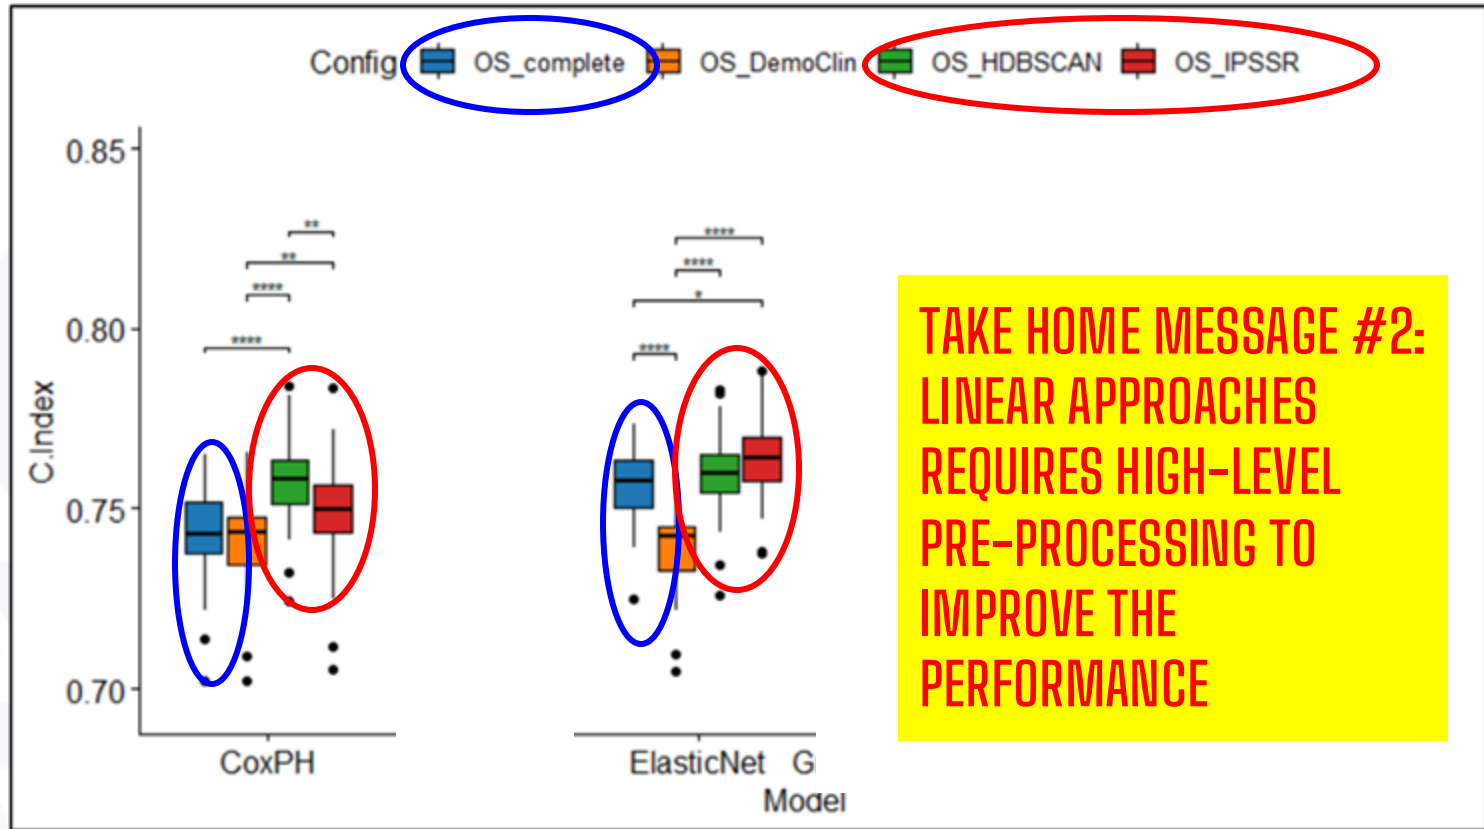

# Results

# Results

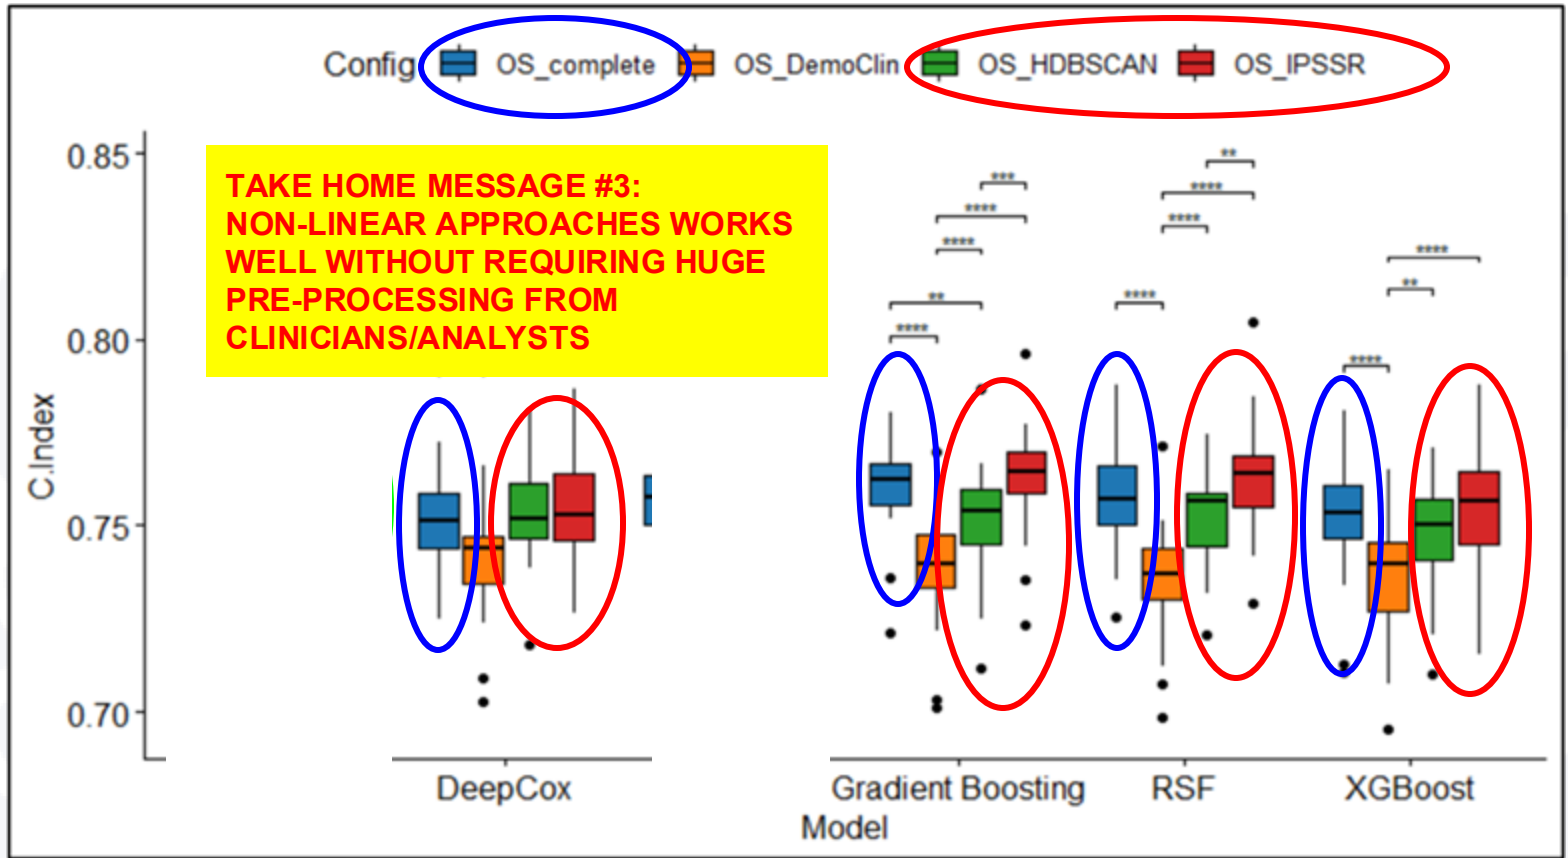

# Results

**TAKE HOME MESSAGE #2:**  
LINEAR APPROACHES  
REQUIRES HIGH-LEVEL  
PRE-PROCESSING TO  
IMPROVE THE  
PERFORMANCE

# Results

# Combining unsupervised and supervised approaches

## ❖ Myelodysplastic syndromes complexity:

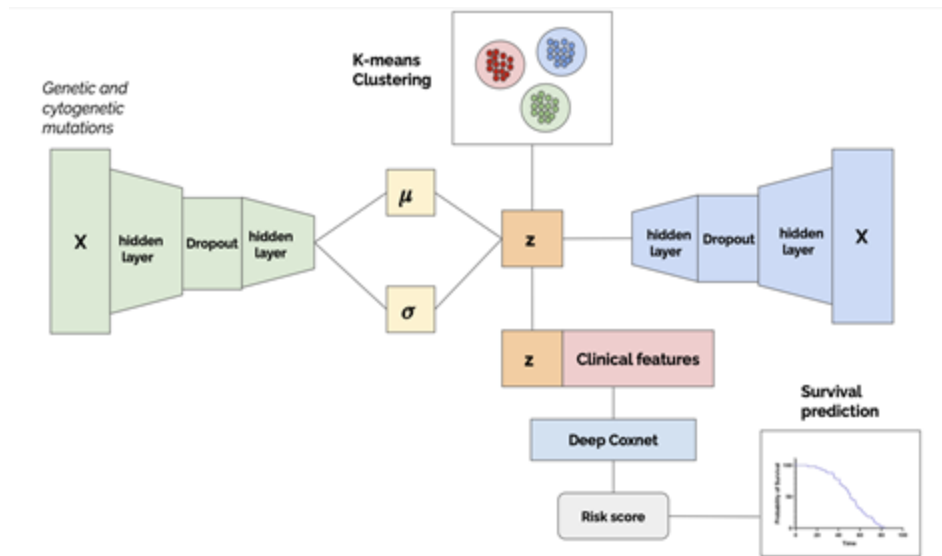

- Heterogeneous group of hematopoietic stem cells disorders
- Intricate genetic mutational landscape (point mutations, chromosomal deletions, translocations)
- Possible progression into Amyotrophic lateral sclerosis (AML)
- Heterogeneous survival rates

- ❑ A precise classification of **MDS subtypes** is required (WHO 2016)
- ❑ **Prognosis prediction** is challenging
- ❑ **Risk stratification** that includes genetic and cytogenetics information

# VAE-Surv Framework for MDS

- ❖ The aim of the proposed model is to build an end-to-end framework that allows the prediction of patients' prognosis and identify genetic-based clusters of the disease
- ❖ The VAE block is trained using only genetic and cytogenetic information
- ❖ The learned latent representation is concatenated with clinical features and used to feed a DeepSurv neural network in a separate step for survival analysis prediction

# VAE-Surv Framework for MDS

# Making the results interpretable to clinicians

## ❖ Explainability

It is possible to detect the main features affecting the progression in **EACH PATIENT SEPARATELY**

# Next Steps

## ❖ Sickle cell disease:

- A cohort of **1000 patients** (500 adults and 500 pediatric) from 5 different healthcare institutions has been collected → Data will be released by the end of the year
- It will include longitudinal clinical data, as well as genomic and metabolomic features
- One of the main clinical outcomes to predict will be the **Silent Cerebral Infarct (SCI)** event → MRI data available

## ❖ Multiple Myeloma:

- A supplementary cohort of **176 patients** (in addition to the 100 patients already collected) will be shared by the Genomed4All consortium
- Data will include clinical features and Copy Number Variation (**CNV**) information
- Radiomic data (PET derived) will be parallelly analysed by University of Bologna

## ❖ Federated learning algorithm already validated on synthetic data will be applied to **real-world scenarios**

# Federated Learning

Unleashing the Power of Collaborative Intelligence

How to achieve faster advances in medical research?

# Introduction

## Transforming Medicine with Federated Learning: An Indispensable Need

Data privacy

Global Collaboration

Treatment Personalization

Research Acceleration

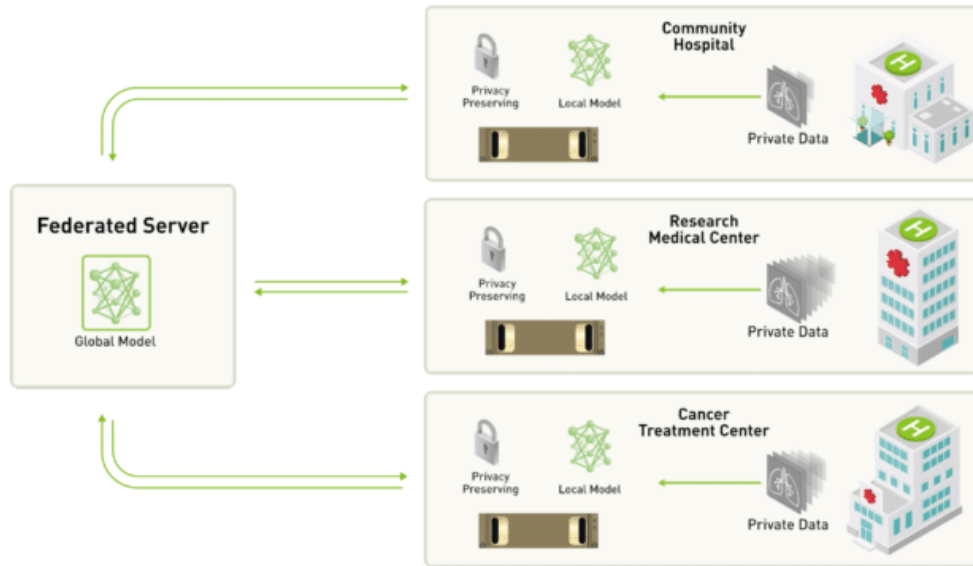

Costs Reduction

# Definition

## What is Federated Learning?

**Federated Learning** is a decentralized machine learning approach that enables training models on distributed data without the need for data sharing, bringing privacy and scalability benefits to the field of AI.

### Process

1. Model and task selection
2. Local training with local data
3. Performance update
4. Global aggregation
5. Repeat steps 2, 3, 4

# Challenges

## Implementation of Federated Learning environments

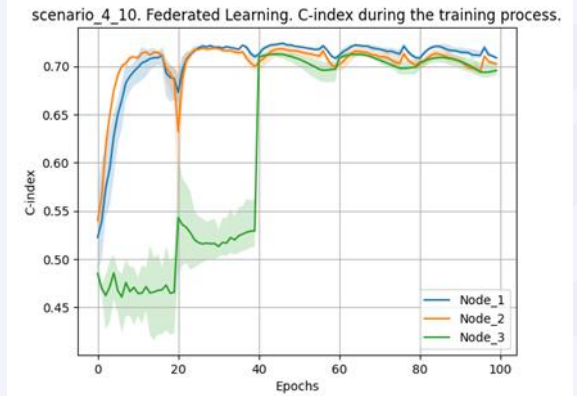

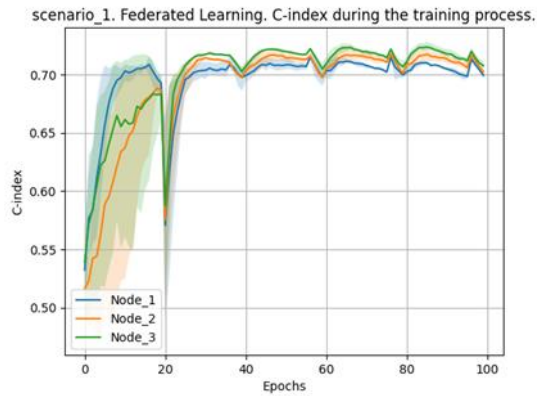

- ☐ Privacy and Security
- ☐ Communication and Bandwidth
- ☐ Model Coordination and Aggregation
- ☐ Data Heterogeneity
- ☐ Latency
- ☐ Refusal to participate
- ☐ Model evaluation

A careful approach to the design and implementation of Federated Learning systems is **essential**

# Genomed4ALL results

## MDS results in a FL environment

C-index value for each experiment. The higher value, the better performance.

Scenario\_1: All participants have the same quantity and quality of data

Scenario\_4: Participant 3 has less quantity (100 or 10 samples) and quality of data

# Genomed4ALL results

## MM results in a FL environment

Scenarios	Nodes	Therapy 1 (iso - fed)	Therapy 2 (iso - fed)	Therapy 3 (iso - fed)
Scenario 1	Node 1	0.28 – <b>0.40</b>	0.79 – <b>0.80</b>	0.82 – <b>0.86</b>
	Node 2	0.22 – <b>0.40</b>	0.76 – <b>0.80</b>	0.83 – <b>0.86</b>
	Node 3	0.36 – <b>0.40</b>	0.74 – <b>0.80</b>	0.80 – <b>0.86</b>
Scenario 3_10	Node 1	0.28 – <b>0.40</b>	0.79 – 0.75	0.82 – 0.81
	Node 2	0.22 – <b>0.40</b>	0.66 – <b>0.75</b>	0.79 – <b>0.81</b>
	Node 3	0.09 – <b>0.40</b>	0.77 – 0.75	0.78 – <b>0.81</b>
Scenario 3_50	Node 1	0.28 – <b>0.40</b>	0.79 – 0.75	0.82 – 0.80
	Node 2	0.22 – <b>0.40</b>	0.66 – <b>0.75</b>	0.79 – <b>0.80</b>
	Node 3	0.40 – <b>0.40</b>	0.67 – <b>0.75</b>	0.76 – <b>0.80</b>

F1-score for each experiment. The higher value, the better performance. Bold implies best result.

Scenario\_1: All participants have the same quantity and quality of data

Scenario\_3: Participant 3 has less quantity (10 or 50 samples) and quality of data

# Conclusions

Federated Learning is moving medicine into a more collaborative, safe and efficient future.

# Federated learning applied to clinical data

Federated learning:

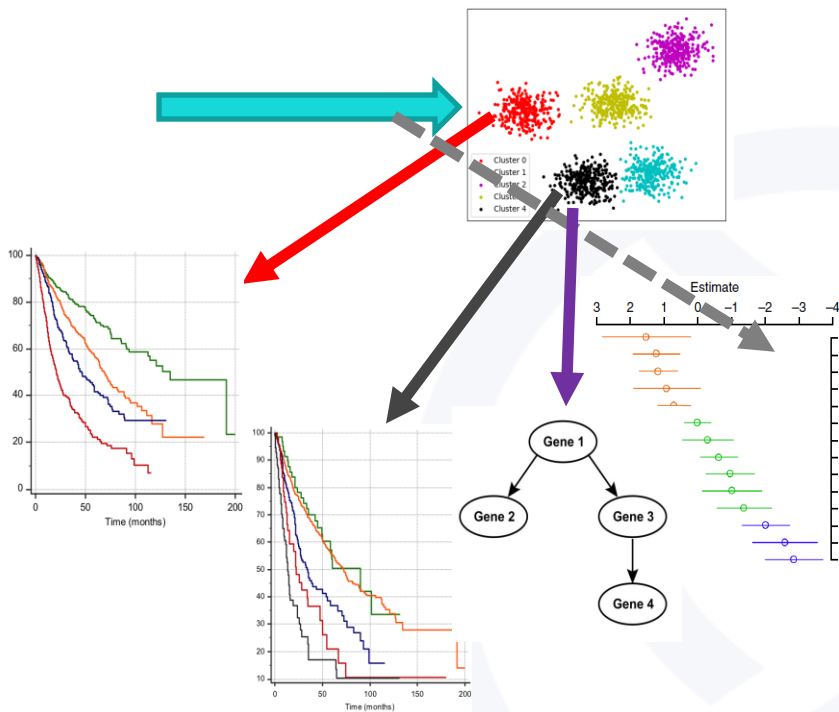

- ❑ data are kept with the data contributor (“edges” or “nodes”)
- ❑ **computing is performed at the site of local data storage**
- ❑ parameter settings are orchestrated and “learned” by a central parameter server

Cytogenetic, genetic and  
clinical data  
(VAF, TD, CNV etc)

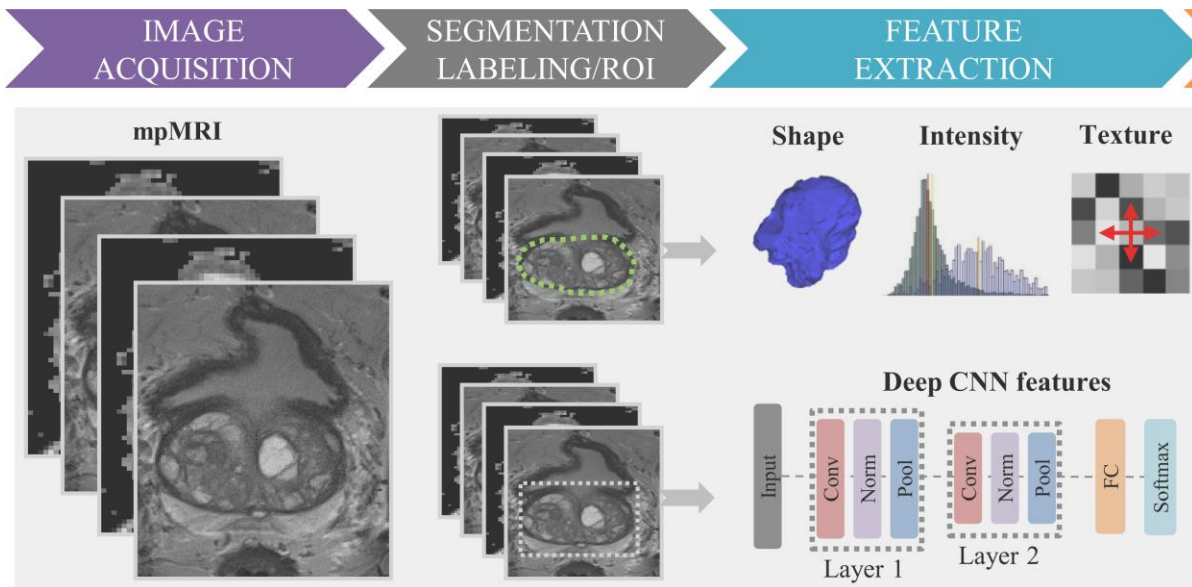

Clustering with HDP  
&

Clonality/Subclonality with  
B&T and mutation timing

Driver Mutations (BN Causality)  
Patient Stratification (HDP)  
Survival analysis

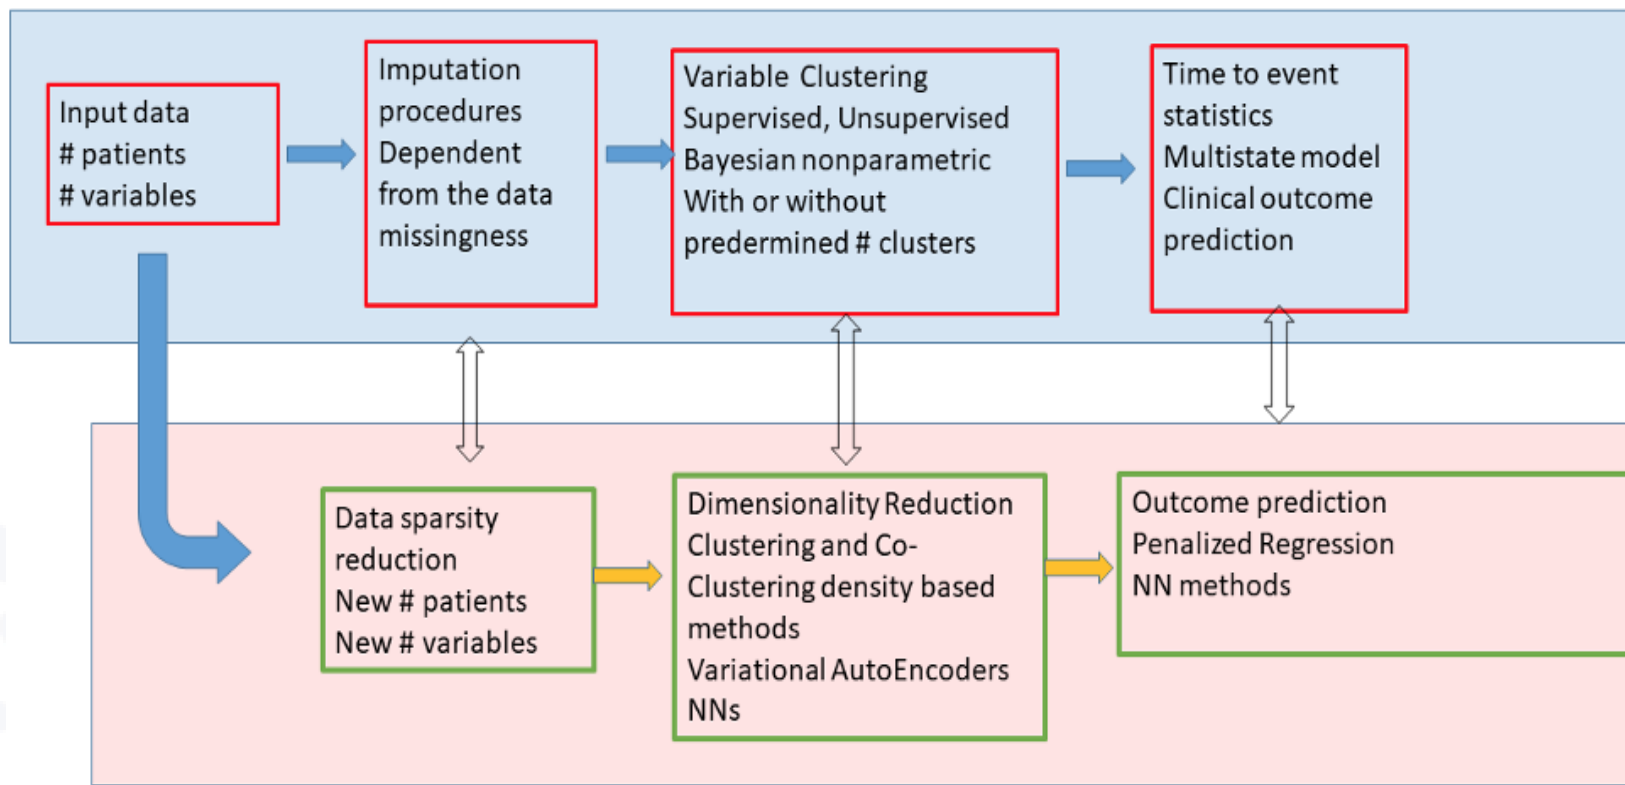

# Radiomics

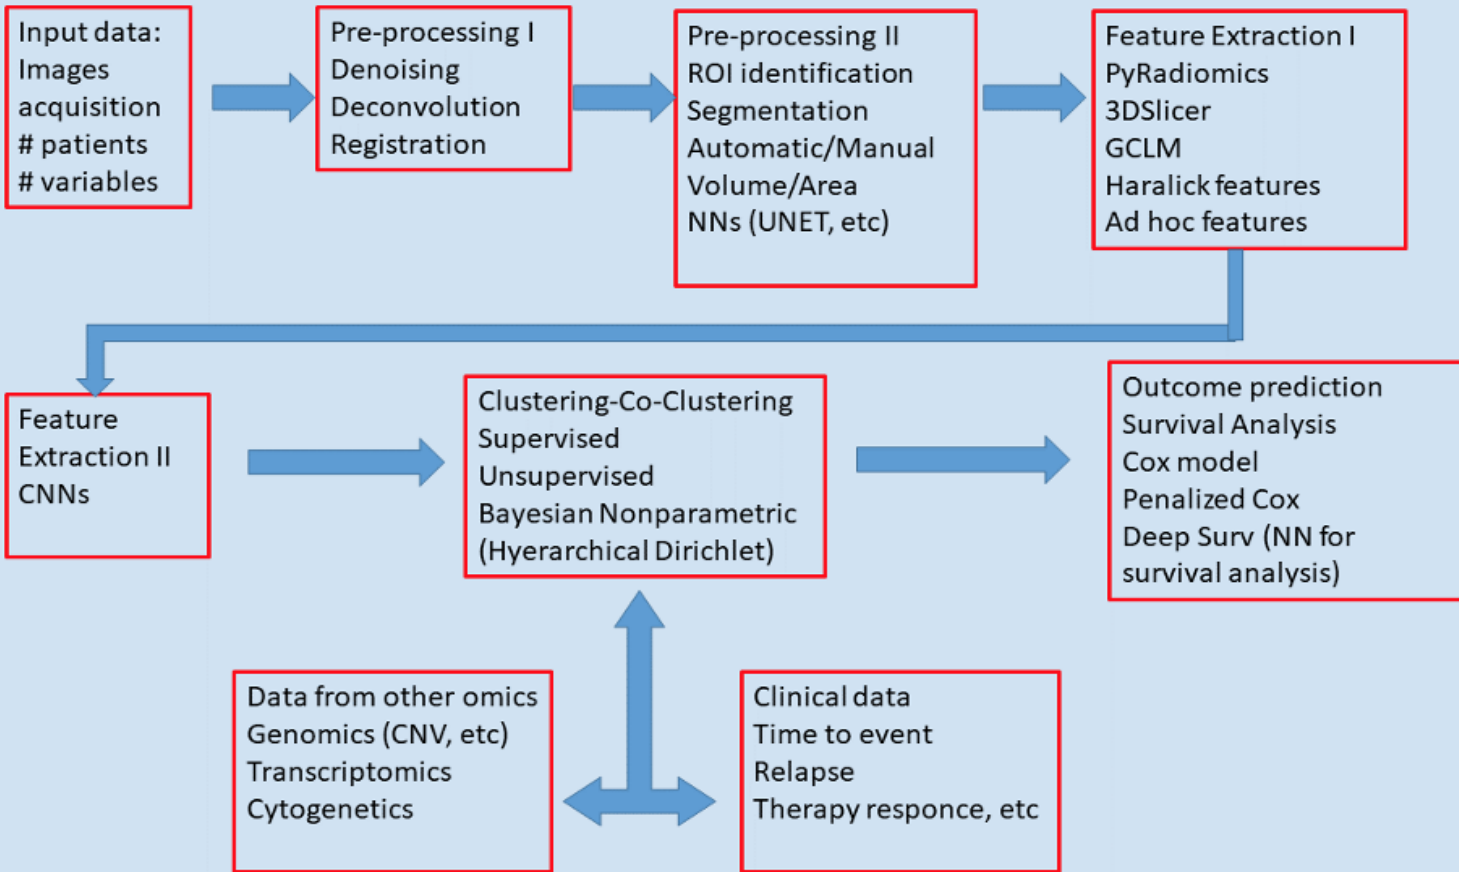

- Aims to extract quantitative, and ideally reproducible, information from diagnostic images.
- Includes complex pattern difficult to recognize and quantify by the human eye

**Pipeline for clinical and genomic data (MDS and MM).** The choice between imputation data sparsity reduction depends from the mechanisms of missingness. After the imputation step, dimensionality reduction and/or data clustering are used to identify a putative patient stratification

**Pipeline for radiomic data (SCD, MM).** Main steps for integrating imaging with clinical and genomic data

# Two example of skeleton segmentation (CT)

# CT segmentation superimposed on PET

Kaplan-Meier curves for  
PFS (patients stratified by  
presence  
of PM disease)

# Segmentation of White Matter Hyperintensities (UNIBO and UNIPD)

(WMH on FLAIR images of patient affected by Sickle Cell Disease(SCD))

- Similar to the Multiple Sclerosis Lesions
- Lesions Can be very small
- Many tools for MS lesions segmentation
- Tool for MS can be adapted to SCD case

## Pre-Trained UNet1:

- Winner of MICCAI WMH Segmentation Challenge
- Many False Positives(FP)

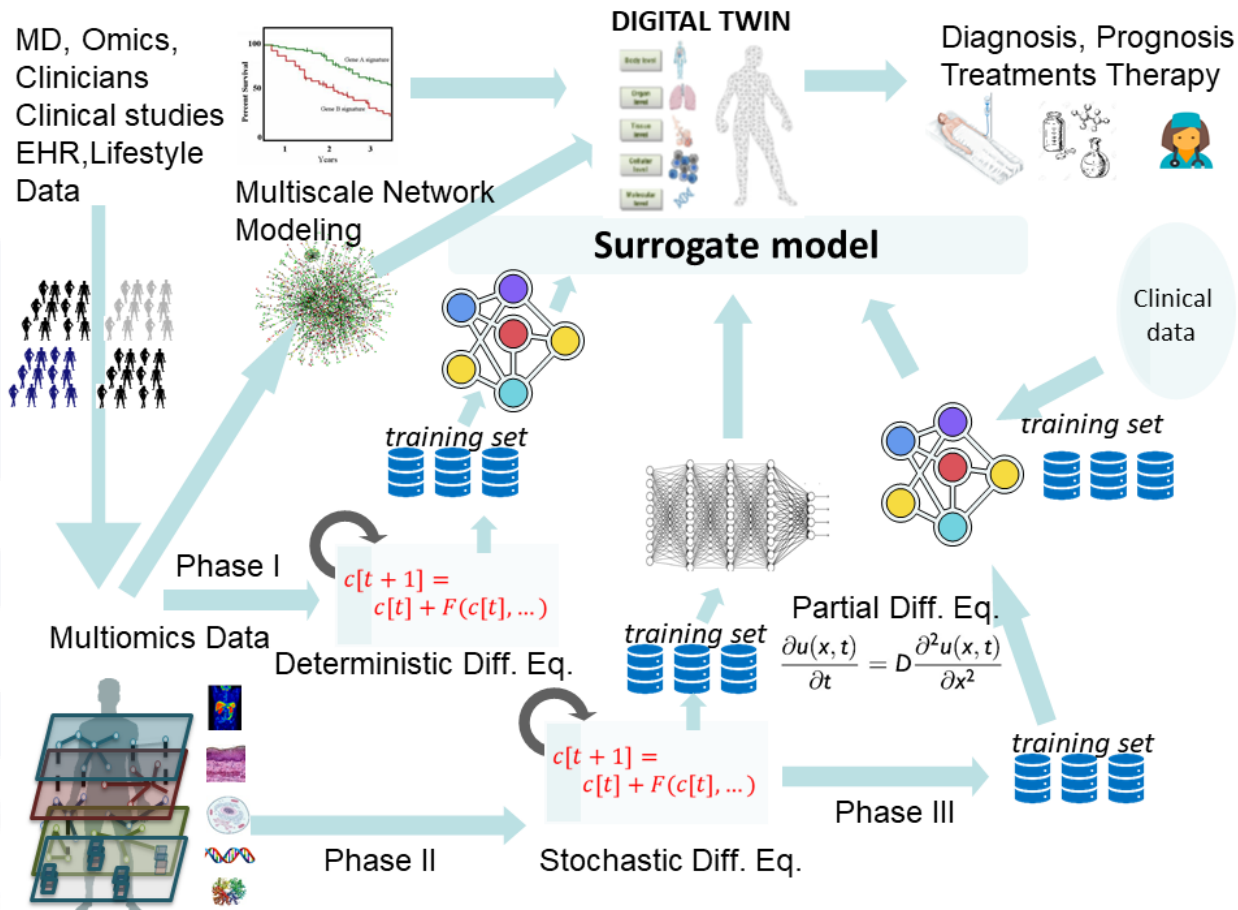

## Adapt the Network:

- Removal of False Positives
- Lesion Area Enlargement

FLAIR image of a patient affected by SCD.  
We have highlight the WMH lesion areas

1 Fully Convolutional Network Ensembles for White Matter Hyperintensities Segmentation in MR Images, H.Li et al. NeuroImage, 2018
